

# The Energy Mashup Lab

## Common Transactive Services 1.0

### The Energy Mashup Lab Draft Specification

#### Draft of 28 October 2020

##### Editor:

William T. Cox ([cto@theenergymashuplab.org](mailto:cto@theenergymashuplab.org) [wtcov@coxsoftwarearchitects.com](mailto:wtcov@coxsoftwarearchitects.com))

Toby Considine ([director@theenergymashuplab.org](mailto:director@theenergymashuplab.org) [toby.considine@gmail.com](mailto:toby.considine@gmail.com))

##### Additional artifacts:

This prose specification is one component of a Work Product that also includes:

- UML models
- JSON schemas
- Simple Binary Encoding binding (FIX)
- XML schemas

##### Related work:

This specification is related to:

- OASIS Energy Interoperation v1.0 (OASIS Standard)
- OASIS WS-Calendar Platform-Independent Model v1.0
- OASIS WS-Calendar Streams v1.0

##### Abstract:

TBD

##### Status:

This document is produced by The Energy Mashup Lab

## 143 1 Introduction

144 Common Transactive Services (CTS) allows actor interaction with any market. Technically, CTS  
145 is a streamlined and simplified profile of the OASIS Energy Interoperation (EI) specification,  
146 which describes an information and communication model to coordinate energy between any two  
147 parties, such as energy suppliers and customers, markets and service providers.

148 Transactive Resource Management (TRM) has been used for many non-energy resources, such  
149 as water delivery, network bandwidth, and even internet advertising. The initial research in TRM  
150 used a market to allocate heat within a commercial building [TRM]. In TRM, a resource is  
151 defined as a tradable commodity whose value depends on price, location, and time of delivery  
152 [EMIX]<sup>1</sup>. TRM balances supply and demand over time using automated voluntary transactions  
153 between market participants.

154 TRM applied to energy is commonly referred to as Transactive Energy (TE). Neither EI nor CTS  
155 specifies which technologies participants will use; rather they define a technology-agnostic  
156 interface to enable accelerated market development of such technologies.

157 TRM is a means to allocate transactable energy resources including the delivery of commodities  
158 such as electrical energy, electrical power, natural gas, and thermal energy such as steam, hot  
159 water, or chilled water. Transactable energy resources also include the capability to deliver  
160 resources, such as transmission line capacity and flow-rate capacity.<sup>2</sup>

161 The Common Transactive Services are a lightweight profile of the OASIS Energy Interoperation  
162 specification. All CTS messages are simple, and make no assumptions about the systems behind  
163 the messages.

164 The target actors for CTS include but are not limited to

- 165 • Smart Buildings/Homes/Industrial Facility
- 166 • Building systems/devices
- 167 • Business Enterprises
- 168 • Vehicles
- 169 • Microgrids
- 170 • IoT (Internet of Things) devices

171 Transactive Energy has the potential to make our electrical system more efficient, by better  
172 matching supply and demand in real time. TE enable actors to use energy when it is less  
173 expensive and produce energy when it's more valuable, thus reducing reliance on distant  
174 suppliers while maximizing use of local power sources. TE relies on markets and consumer  
175 choice to make better decisions about power supply and use.

176 TE demonstrations and deployments to date have been unique systems—each uses its own  
177 message model and its own market dynamics. Many early implementations required the use of

---

<sup>1</sup> See [http://docs.oasis-open.org/emix/emix/v1.0/cs02/emix-v1.0-cs02.html#\\_Toc319594576](http://docs.oasis-open.org/emix/emix/v1.0/cs02/emix-v1.0-cs02.html#_Toc319594576)

<sup>2</sup> In North American wholesale electricity markets, transmission rights are bought and sold.

178 central or cloud-based markets. Central markets discount local decision making while  
179 introducing new barriers to resilience. Others rely on a single price-setting supplier. None are  
180 interoperable either at the system level or for the actors involved.

181 Turning back to the more general Transactive Resource Management, nothing in CTS restricts its  
182 use to electricity-based markets. Natural gas markets share many characteristics with electricity  
183 markets. Local thermal energy distribution systems can balance electricity markets while having  
184 their own surpluses and shortages.

185 Progress toward TE can be accelerated if a common interaction model is used across systems.  
186 Looked at from another perspective, a client written for a participant in one such system should  
187 be able to interoperate with another TE system. The Common Transactive Services from The  
188 Energy Mashup Lab fulfil that promise.

## 189 **1.1 Generality of the Common Transactive Services**

190 CTS can be used to trade (Tender, Transact on) any [Transactive Resource]. While our focus is  
191 generally on electrical energy or power, in the rest of this document we use **[power]** to mean  
192 *electrical energy or power or any other Transactive Resource*.

193 The actual product in EML-CTS (next section) is implicit in the market with which one  
194 communicates. This limits complexity of product definition to a useful level, so market and  
195 product definition may be considered configuration rather than data.

## 196 **1.2 Application of the Common Transactive Services**

197 The purpose of this specification is to codify the common interactions and messages required for  
198 simple markets, hence for simple transactive energy markets. Any system able to use CTS should  
199 be able to interoperate with any CTS-conforming market with minimal or no change.

200 CTS defines communications between market actors and does not define the market or the  
201 device controls. Autonomous market actors must be able to recognize patterns and make choices  
202 to best support their own needs. Actors need not share details of their internal operations with  
203 others.

204 CTS is valuable for creating micromarkets to manage power within microgrids. Micromarkets  
205 support the capability for dynamic restructuring of grids for fault resilience and efficiency  
206 [GridFaultResilience]. Micromarkets contain complexity by abstracting interactions to the few  
207 common messages of CTS.

208 CTS does not presume a market with a single seller (e.g., a utility). CTS recognizes two parties  
209 to a transaction, and the role of any party can switch from buyer to seller from one transaction to  
210 the next. Each Resource Offer (Tender) has a Buy or Sell side attribute. We assume that when  
211 each transaction is committed (once power has been purchased) it is owned by the purchaser, and  
212 it can be re-sold as desired or needed.

213 A CTS-operated micromarket may balance power over time in a traditional distribution system  
214 attached to a larger power grid or it may bind to and operate a stand-alone autonomous microgrid  
215 [BusinessCase].

### 216 1.3 The EML-CTS System

217 In 2015, the US National Institute for Standards and Technology (NIST) began the Transactive  
218 Energy Modeling and Simulation Challenge (TE Challenge). A report delivered to TE Challenge  
219 in 2016 [CTS2016] defined a minimal subset of Energy Interoperation, which became known as  
220 the Common Transactive Services.

221 In 2019, The Energy Mashup Lab, working with NIST, began developing an open source  
222 software system (Apache 2.0 license) that uses a robust financial or “order book” market for  
223 peer-to-peer transactions. The system architecture separates market interactions from the actors  
224 buying and selling power. The architecture also permits changing the market engine itself. This  
225 system is called EML-CTS and is available today.<sup>3</sup>

226 TE demonstrations have used different market engines, including double auction markets. EML-  
227 CTS was designed to be able to use any (e.g. either, both, or some other market engine) while  
228 keeping interactions between systems and the market unchanged.

229 The EML-CTS 1.0 implementation uses Java class definitions similar to those in the UML in this  
230 specification. Messages are sent using REST POST operations, and JSON serialization uses the  
231 Java classes.

### 232 1.4 Terminology

233 The key words “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”,  
234 “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” in this  
235 document are to be interpreted as described in [RFC2119]

## 301 1.7 Naming Conventions

302 This specification follows some naming conventions for artifacts defined by the specification, as  
 303 follows:

304 For the names of elements and the names of attributes within XSD files and UML models, the  
 305 names follow the lowerCamelCase convention, with all names starting with a lower-case letter.  
 306 For example,

```
307 <element name="componentType" type="ei:ComponentType"/>
```

308 For the names of types within XSD files, the names follow the UpperCamelCase convention  
 309 with all names starting with a lower-case letter prefixed by “type-“. For example,

```
310 <complexType name="ComponentServiceType">
```

311 For clarity in UML models the suffix “type” is not always used.

312 For the names of intents, the names follow the lowerCamelCase convention, with all names  
 313 starting with a lower-case letter, EXCEPT for cases where the intent represents an established  
 314 acronym, in which case the entire name is in upper case.

315 JSON and where possible SBE names follow the same conventions.

## 316 1.8 Editing Conventions

317 For readability, element names in tables appear as separate words. The actual names are  
 318 lowerCamelCase, as specified above, and as they appear in the UML models, and in the XML  
 319 and JSON schemas.

320 All elements in the tables not marked as “optional” are mandatory.

321 Information in the **Meaning** column of the tables is normative. Information appearing in the  
 322 **Notes** column is explanatory and non-normative.<sup>4</sup>

323 Examples and Appendices are non-normative.

## 324 1.9 Architecture

325 Services requests and responses are public actions of each interoperating system. Service actions  
 326 are independent from private actions behind the interface (i.e., device control actions). A service  
 327 is used without needing to know all the details of its implementation. Services are generally paid  
 328 for results, not effort.

---

<sup>4</sup> In ISO and IEC terminology, portions that are not normative are *informative*. We follow the OASIS approach.

329 **1.9.1 Security Considerations**

330 Loose integration using the SOA style assumes careful definition of security requirements  
331 between partners. Size of transactions, costs of failure to perform, confidentiality agreements,  
332 information stewardship, and even changing regulatory requirements can require similar  
333 transactions be expressed within quite different security contexts. It is a feature of the SOA  
334 approach that security is composed in to meet the specific and evolving needs of different  
335 markets and transactions. Security implementation is free to evolve over time and to support  
336 different needs. The Common Transactive Services allow for this composition, without  
337 prescribing any particular security implementation.

338 **1.9.2 CTS Extended Example**

339 As an extended example, using the Common Transactive Services, a microgrid is comprised of a  
340 number of interacting nodes (parties). Those parties interact in a micromarket co-extensive in  
341 scope with the microgrid. No actor reveals any internal mechanisms, but only its interest in  
342 buying and selling power.

343 CTS can also be used for the fractal integration of microgrids. Any micromarket can be bound to  
344 or co-extensive with a node in a larger microgrid. A micromarket participating in this way  
345 exposes only its aggregate market position. Any participant in CTS effectively aggregates  
346 resource it logically contains.

347 In a similar way, in considering a topology of microgrids, any participant in the original  
348 micromarket MAY itself represent a contained autonomous microgrid or, in fact, any  
349 autonomous entity whether or not it is managed in turn by a market.

350 [StructuredEnergy][SmartGridBusiness]

---

## 351 2 Overview of Common Transactive Services

### 352 2.1 Scope of Common Transactive Services

353 CTS engages Transactive Resources, e.g. Distributed Energy Resources (DER) and any provider  
354 or consumer of energy, while making no assumptions as to their processes or technology.

355 This specification supports agreements and transactional obligations, while offering flexibility of  
356 implementation to support specific approaches and goals of the various participants.

357 No particular agreements are endorsed, proposed or required in order to implement this  
358 specification. Energy market operations are beyond the scope of this specification although  
359 interactions that enable management of the actual delivery and acceptance are within scope but  
360 not included in CTS 1.0.<sup>5</sup>

361 As shown in [CTS2016] the Common Transactive Services with suitable product definitions can  
362 be used to communicate with essentially any market.

### 363 2.2 Specific scope statements

364 Interaction patterns and service definitions to support the following are in scope for Common  
365 Transactive Services:

- 366 • Interaction patterns to support transactive energy.
- 367 • Information models for price and product communication.
- 368 • Payload definitions for Common Transactive Services

369 The following are out of scope for Common Transactive Services:

- 370 • Requirements specifying the type of agreement, contract, product definition, or tariff used  
371 by a particular market.
- 372 • Computations or agreements that describe how power is sold into or sold out of a market.

373 Section 1 describes standard bindings, which may be extended by The Energy Mashup Lab or  
374 others in the future.

### 375 2.3 Assumptions

#### 376 2.3.1 Conformance with Energy Interoperation

377 OASIS Energy Interoperation [Energy Interop] Transactive Services is the basis for CTS, which  
378 draws definitions of actors, parties, and transactive interactions from the Energy Interoperation  
379 TEMIX profile.

---

<sup>5</sup> See e.g. Energy Interoperation EiDelivery Service [https://docs.oasis-open.org/energyinterop/ei/v1.0/os/energyinterop-v1.0-os.html#\\_Toc388604056](https://docs.oasis-open.org/energyinterop/ei/v1.0/os/energyinterop-v1.0-os.html#_Toc388604056)

380 Energy Interop assumes an Energy Services Interface (ESI) as the external face of the energy-  
381 consuming or supplying node. Energy Interop defines an interaction model in which there is no  
382 direct interaction across the ESI; this characteristic is shared by CTS.

### 383 **2.3.2 Conformance with EMIX**

384 This specification uses models and artifacts simplified from and in the style of OASIS Energy  
385 Market Information Exchange [EMIX] to communicate product definitions, quantities, and  
386 prices. EMIX provides a succinct way to indicate how prices, quantities, or both vary over time.

387 The EMIX product definition, as included in the Transactive Resource, is implied in CTS 1.0.  
388 Future CTS specifications may include market context from EMIX and EnergyInterop, as well as  
389 other information on products and markets including market terms.

### 390 **2.3.3 Conformance with WS-Calendar Streams**

391 The WS-Calendar specifications<sup>6</sup> express sequences and enables negotiation of schedules in a  
392 manner that is semantically compatible with human schedules, i.e., [iCalendar]. The WS-  
393 Calendar Platform Independent Model (PIM) [WsCalendar-PIM] defines common semantics for  
394 the specifications. WS-Calendar is the standard under the NIST Smart Grid Roadmap for all such  
395 communication.

396 WS-Calendar is used to describe products whose value changes with time of delivery, and again  
397 into Energy Interoperation, which uses Transactive Resources.

398 This specification bases its representation of single intervals on Schedule Signals and Streams  
399 [Streams], a WsCalendar-PIM conforming specification for expressing consecutive occurrences  
400 of schedules or products.

401 CTS 1.0 transacts a single interval at a time, expressed as a single-interval Stream. Energy  
402 systems supported by CTS-based markets may express their requirements and capabilities over  
403 time using multi-interval Streams or in separate single-interval Streams.

### 404 **2.3.4 Compatibility with Facilities Smart Grid Information Model**

405 The Facilities Smart Grid Information Model [FSGIM] was developed to define the power  
406 capabilities and requirements of these systems over time. FSGIM uses the semantics of WS-  
407 Calendar and EMIX to construct its information models for [power] use over time. These  
408 sequences of [power] requirements are referred to as load curves. Load curves can potentially be  
409 relocated in time, perhaps delaying or accelerating the start time to get a more advantageous  
410 price for [power]. These load curves are the basis upon which a TE Agent would base its market  
411 decisions.

412 The Architecture of EML-CTS is premised on distinct physical systems being able to  
413 interoperate by coordinating their production and consumption of **[power]**<sup>7</sup> irrespective of their  
414 ownership, motivations, or internal mechanisms. This specification defines messages and  
415 interactions of that interoperation.

---

<sup>6</sup> See Section 1.5 Normative References

<sup>7</sup> See Section 1.1.

416 CTS transactions are semantically aligned with FSGIM load requests. CTS 1.0 uses Streams to  
417 express single-interval tenders in anticipation of the use of Streams in FSGIM-conformant  
418 communications.

## 419 **2.4 Common Transactive Services Architecture**

420 The implied CTS architecture is drawn from and is a subset and simplification of the architecture  
421 presented in [EnergyInterop]. Specifically, the Energy Interoperation architecture uses the  
422 Service-Oriented Architecture (SOA) model which has become the consensus view for energy.

423 The Energy Mashup Lab uses the Actor Model, which can be implemented in SOA with a few  
424 lightweight Service Operations. The Lab adapted the SOA model of Energy Interoperation into  
425 an Actor-to-Actor model that requires fewer and lighter weight messages.

426 The Actor Model names a style of system integration used for high scalability and resilience.<sup>8</sup>  
427 The Actor Model uses a small number of simple messages to coordinate behavior among simple  
428 agents termed Actors. Note that Actors need not be actually simple; Actors are unable to present  
429 complexity because the messages are so simple.

430 Simple messages are an essential aspect of actor architectures. The Common Transactive  
431 Services are a lightweight profile of the OASIS Energy Interoperation specification. All CTS  
432 messages are simple, and make no assumptions about the systems behind the messages.

433 Just as the market participants present simple messages, so too, does the market. The internals of  
434 a market contain a market engine to match tenders, and to declare contracts. The rules used to  
435 match tenders could be nearly instant order book, or periodic double auction, or some other  
436 model. This complexity is hidden. The market receives tenders and announces contracts. Only  
437 the simple messages of CTS are used.

438 All interactions described in CTS are as defined in [EnergyInterop]. That specification describes  
439 interactions between pairs of actors, and, in a deployment, relationships are established among  
440 actors. Actors may perform in pairwise chains of actors.

441 All interactions and actors below are described as if for Actors in electrical energy markets. For  
442 use in other transactive energy markets, or even transactive resource markets, only the product or  
443 resources would be changed.

444 An actor takes on a role, for example a business role as a Party. In the UML model, *PartyId* and  
445 *CounterPartyId* inherit from *ActorId* which in turn inherits from class *UidType*.

### 446 **2.4.1 Sides in Tenders and Transactions**

447 At any moment, a Party has a *position* which represents the cumulative amount of power (or  
448 other product) that an actor has previously transacted for that time interval.

449 A Party can take one of two Sides in a given Transaction:

- 450 • Buy, or

---

<sup>8</sup> See C. Hewitt, "Actor Model of Computation: Scalable Robust Information Systems,"  
arxiv.org, 2010, or C. Hewitt, "A Universal Modular Actor Formalism for Artificial  
Intelligence," ICJA, 1973, or many other references

451           • Sell

452 A Party selling [power] relative to its current position takes the Sell Side of the Transaction. A  
453 Party buying [power] relative to its current position takes the Buy Side of the Transaction.

454 From the perspective of the market, there is no distinction between a party selling additional  
455 power and party selling from its previously acquired position. An Actor representing a generator  
456 generally takes the Sell side of a transaction. An Actor representing a consumer generally takes  
457 the Buy side of a transaction. A generator may take the Buy Side of a Transaction in order to  
458 reduce its own generation, in response either to changes in physical or market conditions or to  
459 reflect reflecting other commitments made by the actor. A consumer may choose to sell from its  
460 current position if its plans change, or if it receives an attractive price. A power storage system  
461 actor may choose to buy or sell from interval to interval, consistent with its operating and  
462 financial goals.

463 We do not specify how the [power] is delivered. For example, a long distance transfer might be  
464 implemented with the seller selling power to its local grid and the buyer buying power from its  
465 local grid, with financial reconciliation producing the same result as a direct sale and deliver.

## 466 **2.4.2 Semantic Composition**

467 The semantics and interactions of CTS are selected from and derived from [EnergyInterop].

468 Energy Interoperation incorporates two other standards, [EMIX] and [WS-Calendar], and uses an  
469 early Streams definition.

- 470           • EMIX describes price and product for electricity markets.
- 471           • WS-Calendar communicates schedules and sequences of operations. This specification  
472 uses the [Streams] optimization which is a standalone specification, rather than part of  
473 Energy Interoperation 1.0.
- 474           • Energy Interoperation uses the vocabulary and information models defined by those  
475 specifications to describe the services that it provides. The payload for each Energy  
476 Interoperation service references a product defined using [EMIX]. EMIX schedules and  
477 sequences are defined using [WS-Calendar]. Any additional schedule-related information  
478 required by [EnergyInterop] is expressed using [WS-Calendar].
- 479           • Since [EnergyInterop] was published, a semantically equivalent but simpler [Streams]  
480 specification was developed in the OASIS WS-Calendar Technical Committee<sup>9</sup>. CTS  
481 uses that simpler [Streams] specification.

482 In effect, CTS is a profile of Energy Interoperation but with simplified information models and  
483 defines only payloads, not the messaging.

484 CTS 1.0 supports a single product market; in other words, product definitions in CTS 1.0 are  
485 implicit. Most markets will be better served with multiple products, for example, a 1-hour market  
486 for power alongside a 5-minute market for power.

487 Future development of CTS may include a discoverable market description profiled from the  
488 EMIX Market Context. The EMIX Market Context defines market rules and catalogs the

---

<sup>9</sup> [https://www.oasis-open.org/committees/tc\\_home.php?wg\\_abbrev=ws-calendar](https://www.oasis-open.org/committees/tc_home.php?wg_abbrev=ws-calendar)

489 products tradeable in the market. Future versions of CTS will support multiple markets, hence  
490 multiple products.

491 All terms used in this specification are as defined in their respective specifications.

## 492 **2.5 Products and Instruments**

493 A CTS Product is a specific resource packaged in a specific quantity for a specific duration. An  
494 example is 10 kW of power over the duration of an hour. An actor wanting to buy or sell 100 kW  
495 of power during an hour would tender 10 units of that product.

496 The CTS architecture transacts in power products at specific times, referred to as Instruments.

497 Tenders become Contracts when a tender to buy a product at a specific time, and a tender to sell  
498 a product at that same specific time are matched. These are two tenders for the same instrument

---

## 499 3 Services and Operations

500 This section re-iterates terms and simpler models from [Energy Interop]. That specification is  
501 normative.

502 For each service operation there is an actor that *invokes* the service operation and one that  
503 *provides* the service. These roles are indicated by the table headings *Service Consumer* for the  
504 actor or role that consumes or invokes the service operation named in the *Operation* column and  
505 *Service Provider* for the actor or role that provides or implements the service operation as named  
506 in the *Operation* column.

507 This terminology is used through all service definitions presented in this specification.

508 The column labeled *Response Operation* lists the name of the service operation invoked as a  
509 response. Most operations have a response, excepting primarily those operations that broadcast  
510 messages. The roles of *Service Consumer* and *Service Provider* are reversed for the *Response*  
511 *Operation*.

512 For transactive services any party may receive tenders (priced offers) of service and possibly  
513 make tenders (priced offers) of service.

514 Any party using transactive energy services may own generation or distributed generation or  
515 reduce or increase energy from previously transacted energy amounts. These activities are not  
516 identified in transactive services. The dispatch of these resources and the use of energy by a  
517 party are influenced by tenders between Parties that may result in new Transactions and changes  
518 in operations.

519 The next section describes the roles in a transactive approach tendering and prices are used by  
520 parties to discover and negotiate transactions that respect the preferences of each party and  
521 energy usage, generation, storage and controllability directly available to each party.

### 522 3.1 Structure of Common Transactive Services and Operations

523 The Common Transactive Services presented in this specification are only

- 524 • Transactive Services—for implementing transactions and tenders

525 We include UML definitions for the standard payloads for service requests, rather than the  
526 service, communication, or other characteristics. In Section 5 we describe standard serialization  
527 for the CTS standard payloads; additional bindings may be used by conforming implementations.

### 528 3.2 Naming of Services and Operations

529 The naming of services and operations follows a pattern. Services are named starting with the  
530 letters *Ei* following the Upper Camel Case convention. Operations in each service use one or  
531 more of the following patterns. The first listed is a fragment of the name of the initial service  
532 operation; the second is a fragment of the name of the response message which acknowledges  
533 receipt, describes errors, and may pass information back to the invoker of the first operation.

534 *Create—Created* An object is created and sent to the other Party

535 *Cancel—Canceled* A previously created request is canceled

536 For example, to construct an operation name for the EiEvent service, "Ei" is concatenated with  
537 the name fragment (verb) as listed. For example, an operation to cancel an outstanding Tender is  
538 called *EiCancelTender*.

### 539 **3.3 Payloads and Messages**

540 We define only the payloads; the particular networking technique and message structure is  
541 determined by the applications sending and receiving CTS payloads.

### 542 **3.4 Description of the Services and Operations**

543 The sections below provide the following for each service:

- 544 • Service description
- 545 • Table of operations
- 546 • Interaction patterns for the service operations in graphic form
- 547 • Information model using [UML] for key artifacts used by the service
- 548 • Operation payloads using [UML] for each operation

### 549 **3.5 Responses**

550 In a service interaction, responses may need to be tracked to determine if the transaction is  
551 successful or not. This may be complicated by the fact that any given transaction may involve  
552 the transmission of one or more information objects.

553 A Response returns the success or failure of the entire operation, with possible detail included if  
554 there is more than one bundled operation (e.g. EiCancelTender with multiple tenders).

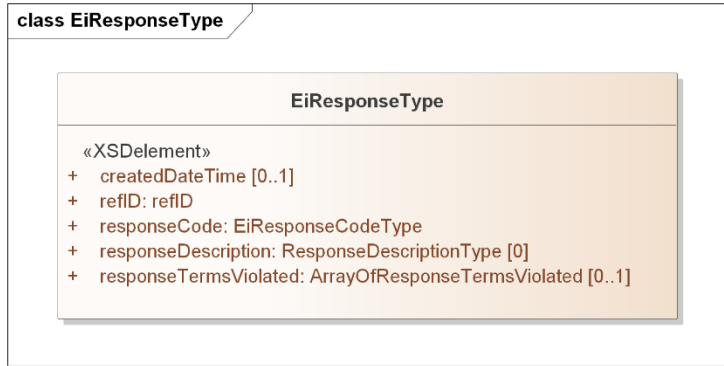

555 It is MANDATORY to return errors in responses. It is MANDATORY in CTS to return  
556 successes in responses.<sup>10</sup>

557 The class diagram reflects the generic response in CTS 1.0.

558 The description of EiResponseType is from Energy Interoperation, changing only the cardinality  
559 of responseDescription (to zero, that is, not passed).

---

<sup>10</sup> This contrasts with Energy Interoperation, where it is not mandatory to return any responses if the entire EiCancelTender service operation was completed successfully. The pattern in Energy Interoperation is to return those that have failed (required) and those that succeeded (optional).

560

561 *Figure 3-1: Example of generic error response for a service operation*

562 The attributes of EiResponseType are in the following table.

563 *Table 3-1: EiResponse Attributes*

Attribute	Meaning	Notes
Created DateTime	Optional timestamp indicating the date and time when this EiResponse was created	
RefId	Reference ID which identifies the artifact or message element to which this is a response. refId serves as a correlation ID <sup>11</sup> .	
Response Code	<p>The Response Code indicates success or failure of the operation requested. The Response Description is unconstrained text, perhaps for use in a user interface.</p> <p>The code ranges are those used for HTTP response codes,<sup>12</sup> specifically</p> <p>1xx: Informational - Request received, continuing process</p> <p>2xx: Success - The action was successfully received, understood, and accepted</p> <p>3xx: Pending - Further action must be taken in order to complete the request</p> <p>4xx: Requester Error - The request contains bad syntax or cannot be fulfilled</p> <p>5xx: Responder Error - The responder failed to fulfill an apparently valid request</p>	
Response Description	The Response Description is in the model but profiled to be cardinality 0..0.	Not present in CTS 1.0 payloads

<sup>11</sup> As an example of the *Correlation Pattern* for messages

<sup>12</sup> See e.g. [https://en.wikipedia.org/wiki/List\\_of\\_HTTP\\_status\\_codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes)

Response Terms Violated	The Terms Violated by the request to which this is a response. Conforming CTS 1.0 implementations SHALL omit this attribute.	Market Terms and Market Context may be implemented in a future release.
-------------------------	--	---

564

565 There is no exhaustive list of all possible Response Codes. The Response Codes are intended to  
 566 enable even the smallest device to interpret Response. This specification uses a pattern consisting  
 567 of a 3-digit code, with the most significant digit sufficient to interpret success or failure. This  
 568 pattern is intended to support that smallest device, while still supporting more nuanced messages  
 569 that may be developed.

570 While the only value after the leading digit the Response Code defined in Energy Interoperation  
 571 is 00, conforming specifications may extend these codes to define more fine-grained response  
 572 codes. These should extend the pattern above, though. A response code such as 403 should  
 573 always be within the realm of Requester Error.

574 EML-CTS uses error code 200 for success.

---

## 575 4 Transactive Services

576 Transactive Services define and support the lifecycle of transactions from initial Tender to final  
577 settlement. The phases described in [Energy Interop] are

- 578 • Registration—to enable further phases. (Not part of CTS)
- 579 • Pre-Transaction —binding tenders for transactions. (Part of CTS)
- 580 • Transaction Services—execution and management of transactions. (Part of CTS)
- 581 • Post-Transaction—settlement, energy used or demanded, payment, position. (Not part of  
582 CTS)

583 For transactive services, the roles are **Parties** and **Counterparties**.

584 The terminology of this section is that of business agreements: tenders and transaction. The  
585 Service descriptions and payloads are simplified and updated from those defined in Energy  
586 Interoperation.

### 587 4.1 Pre-Transaction Services

588 Pre-transaction services are those between parties that may prepare for a transaction. The service  
589 in CTS is EiTender with two service operations.

590 Tenders and transactions are artifacts based on [EMIX] artifacts suitably flattened and  
591 simplified, and which contain schedules and prices in varying degrees of specificity or  
592 concreteness.

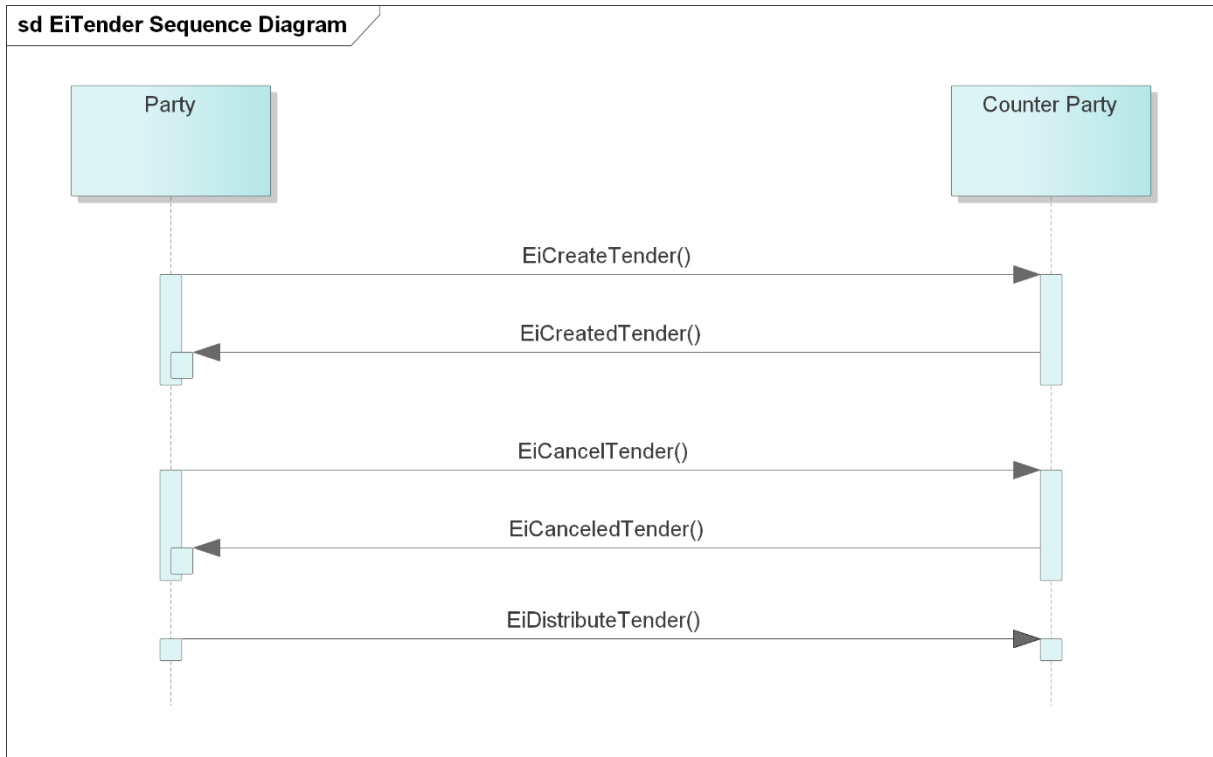

593 *Table 4-1: Pre-Transaction Tender Services*

Service	Operation	Response	Service Consumer	Service Provider	Notes
EiTender	EiCreateTender	EiCreatedTender	Party	Party	Create and send Tender
EiTender	EiCancelTender	EiCanceledTender	Party	Party	Cancel one or more Tenders

594

#### 595 4.1.1 Interaction Pattern for the EiTender Service

596 Figure 4-1 presents the [UML] sequence diagram for the EiTender Service. Note that  
597 EiDistributeTender is not part of CTS 1.0, but is being considered for a future release.

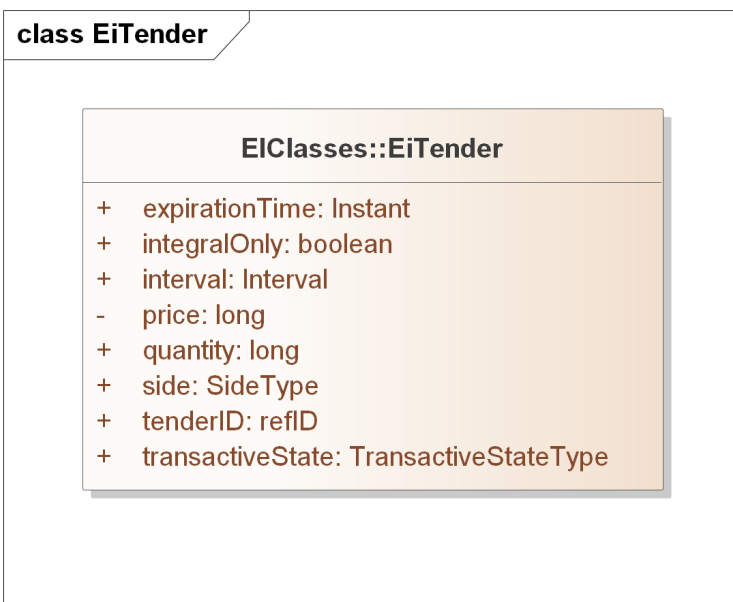

598

599 *Figure 4-1: UML Sequence Diagram for the EiTender Service*

600 **4.1.2 Information Model for the EiTender Services**

601 The information model for the EiTender Service artifacts follows that of [EMIX], but flattened  
 602 and with product definition implied by the implementation.

603 Time interval, price, and quantity are key elements for a product; the other aspects of product  
 604 definition (e.g. energy and units) are implicit as described in Section 2.4.2.

605

606 *Figure 4-2: Class EiTenderType*

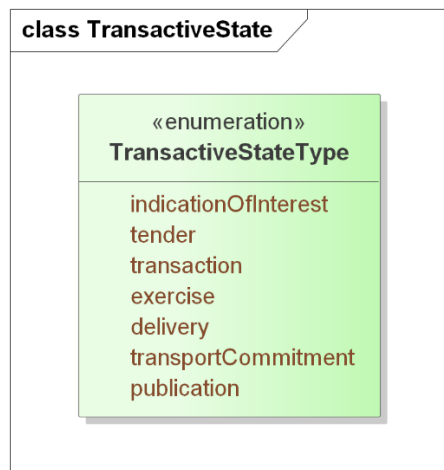

607 The attributes of EiTender are shown in the following table.

608 Table 4-2: EiResponse Attributes

Attribute	Meaning	Notes
Expiration Time	The date and time after which this Tender is no longer valid.	
Integral Only	All of the Tender must be bought or sold at once; no partial sale or purchase	In EML-CTS set to False
Interval	The time interval for the product being offered	
Price	The unit price for the product being offered	Total price is the product of price and quantity
Quantity	The quantity of the product being offered	Total price is the product of price and quantity
Side	Whether the tender is to buy or to sell the product	
Tender ID	An ID for this tender	
Transactive State	The transactive state of this payload (tender)	See below

609

610 Transactive State is a concept from EMIX; it describes the state of an object. For CTS 1.0, only  
611 states *tender* and *transaction* are used.

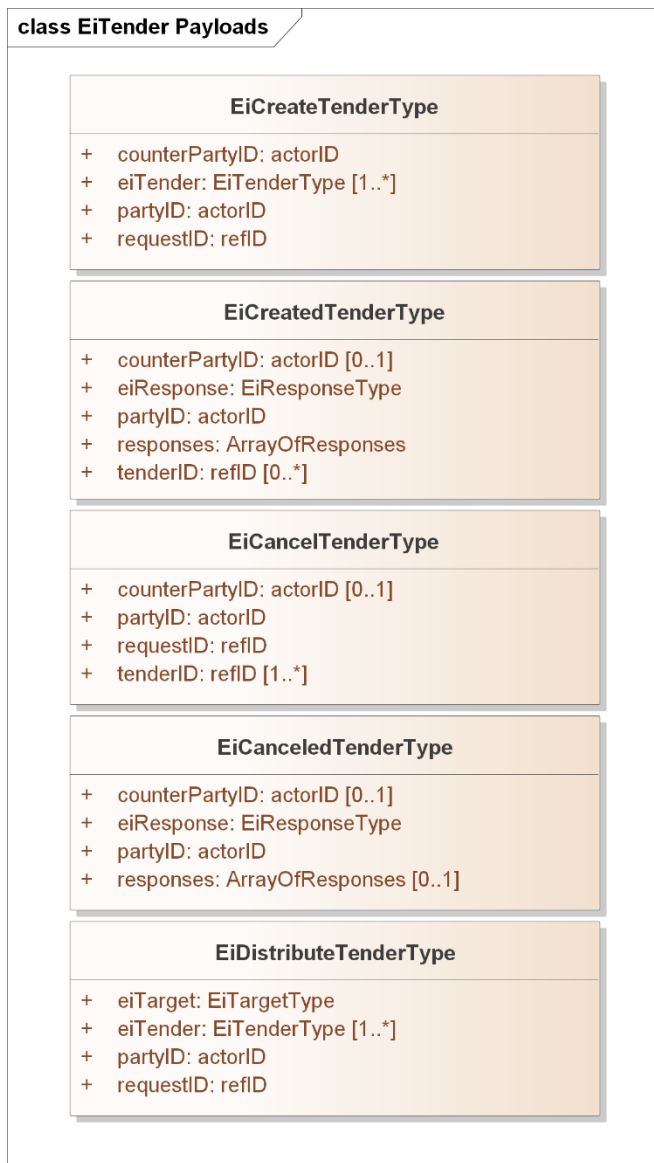

612

613 Figure 3-3: Enumeration TransactiveStateType

614 **4.1.3 Operation Payloads for the EiTender Service**

615 The [UML] class diagram describes the payloads for the EiTender service operations.

616  
617 *Figure 4-4: UML Class Diagram for the Operation Payloads for the EiTender Service*

618 **4.2 Transaction Management Services**

619 The service operations in this section manage the exchange of transactions. The context is  
620 implied, or may in the future be made explicit with a Market Context reference (see Section  
621 2.4.2). Note that canceling or modifying transactions are not included in either CTS or Energy

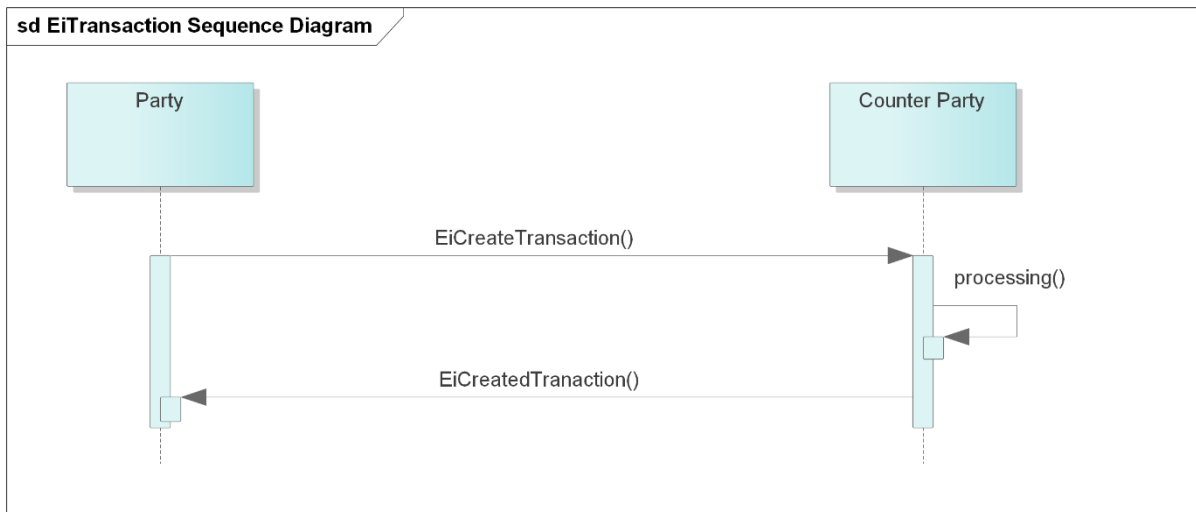

622 Interoperation. Following the approach in distributed agreement protocols<sup>13</sup>, a compensating  
 623 transaction SHOULD be created as needed to compensate for any effects.<sup>14</sup>

624 *Table 4-3: Transaction Management Service*

Service	Operation	Response	Service Consumer	Service Provider	Notes
EiTransaction	EiCreateTransaction	EiCreatedTransaction	Party	Party	Create and send Transaction

625 **4.2.1 Interaction Pattern for the EiTransaction Service**

626 This is the [UML] sequence diagram for the EiTransaction Service:

627  
 628 *Figure 4-5: UML Sequence Diagram for the EiTransaction Service*

629 **4.2.2 Information Model for the EiTransaction Service**

630 Transactions are derived from [EMIX] artifacts including a Stream with time, quantity, and  
 631 price. Flattening similar to that in EiTender is used.

632 Although an EiTransaction object includes the original EiTender, the EiTransaction carries its  
 633 own Transactive State.

<sup>13</sup> See, e.g., WS-Transaction and WS-BusinessActivity.

<sup>14</sup> This is consistent with the way that distributed agreement protocols such as [WS-BusinessActivity] manage compensation rather than cancelation.

634

635 *Figure 4-6: UML Class Diagram of EiTransaction*

636 The attributes of EiTransaction are shown in the following table.

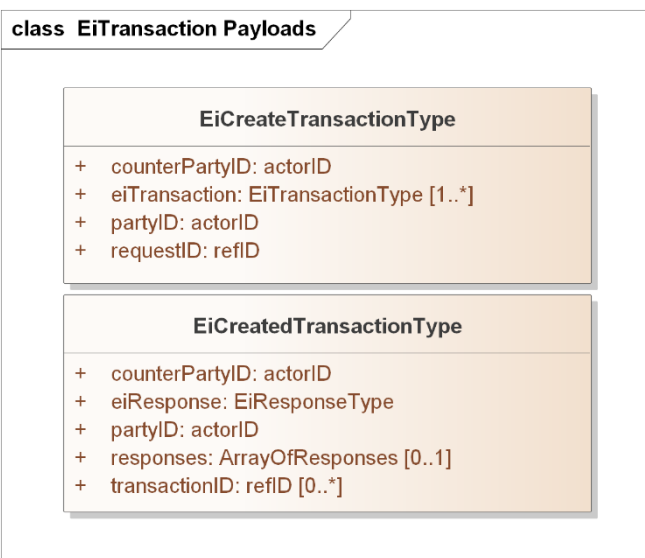

637 *Table 4-4: EiTransaction Attributes*

Attribute	Meaning	Notes
Tender	The EiTender that led to this Transaction.	The ID, quantity and price may differ from that originally tendered due to market actions.
Transaction ID	An ID for this Transaction	The contained Tender has its own TenderID
Transactive State	The transactive state of this payload (transaction)	See Figure 3-3: Enumeration TransactiveStateType

638

### 639 4.2.3 Operation Payloads for the EiTransaction Service

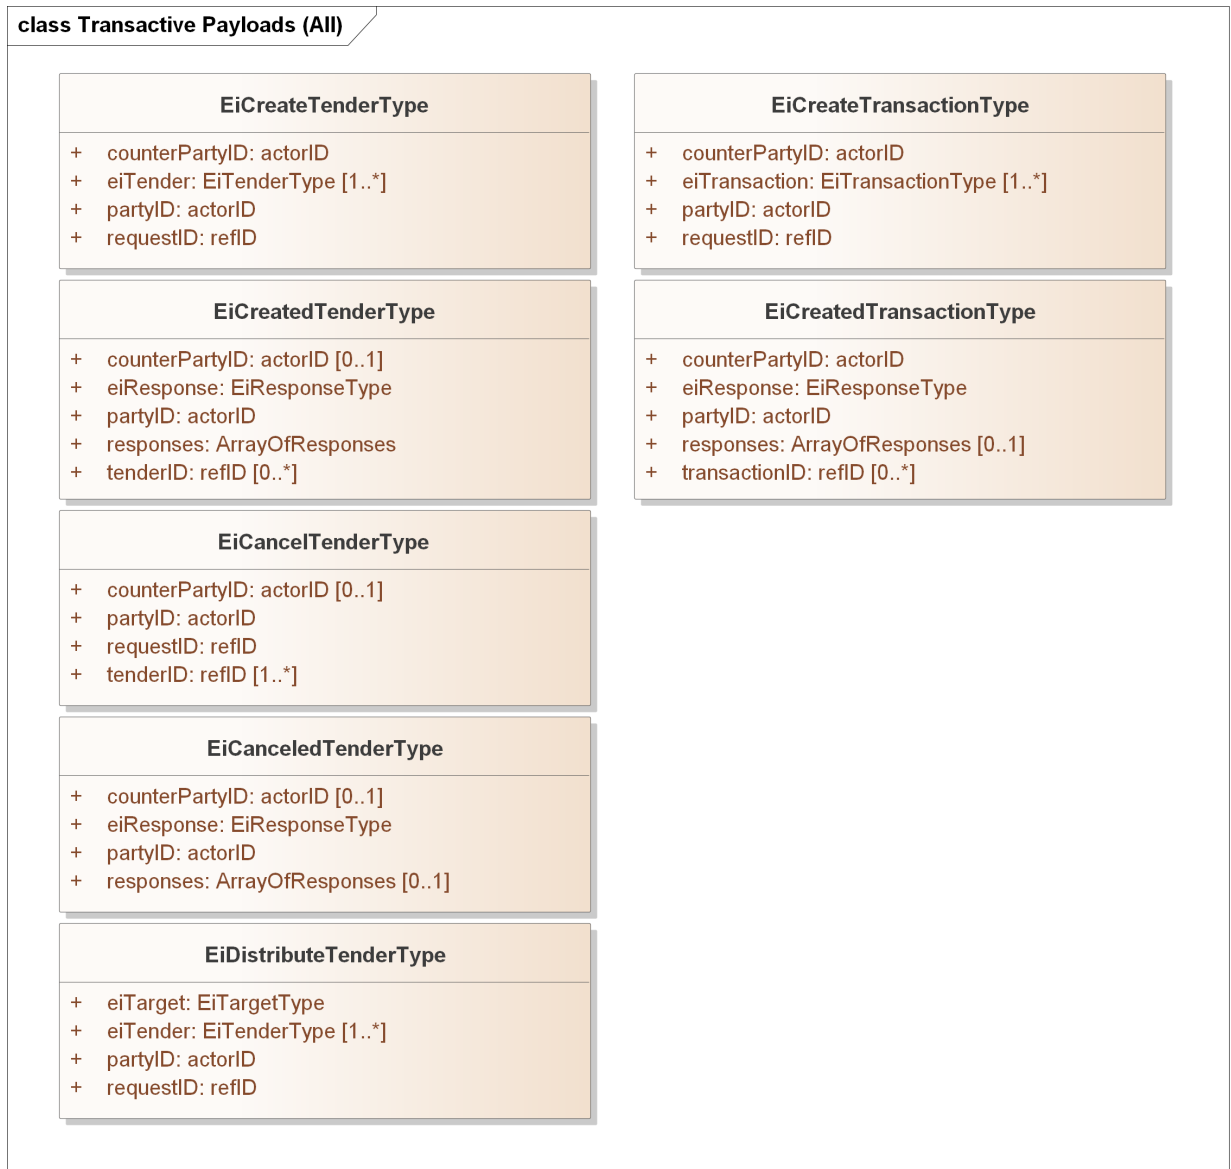

640 The [UML] class diagram describes the payloads for the EiTransaction service operations.

641

642 *Figure 4-7: UML Class Diagram of EiTransaction Service Operation Payloads*

643 **4.3 Comparison of Transactive Payloads**

644  
645 *Figure 4-8: UML Diagram comparing all Transactive Payloads*

646

---

## 647 **5 Bindings**

648 Payloads and interaction patterns are described in [UML] in Section 1 above. This section  
649 contains bindings for the payloads in three encoding schemes:

- 650 • JSON [JSON]
- 651 • XML Schema [XSD]
- 652 • FIX Simple Binary Encoding [SBE]

### 653 **5.1 JSON**

654 TODO—JSON Schema available

### 655 **5.2 XML Schema**

656 TODO—XML Schema available

#### 657 **5.2.1 XML Namespaces**

### 658 **5.3 Simple Binary Encoding**

659 TODO—Work in progress

---

660 **6 Conformance and Processing Rules for Common**

661 **Transactive Services**

662 **TODO update in progress**

---

## 663 **7 Conformance Statements**

664 The Common Transactive Services conform to the base standards as follows.

665 This section includes conformance statements for the Common Transactive Systems to

- 666 • OASIS Energy Interoperation 1.0
- 667 • OASIS WS-Calendar MIN
- 668 • OASIS WS-Calendar Schedule Streams and Signals

---

## 669 Appendix A. Acknowledgments

670 This specification began with William Cox leading the Common Transactive Services team in  
671 the 2015-2016 NIST Transactive Energy Challenge to define the initial structure of the CTS  
672 [CTS2016].

673 Others picked up and used that work, culminating in a contract from NIST with TC9, Inc and  
674 Cox Software Architects LLC to develop agents to support co-simulation of bilateral markets  
675 with GridLAB-D™ input models in the NIST Cyberphysical systems modelling platform. That  
676 contract required all work to be open source from day one, and all work to be done in the open.  
677 TC9 opted to perform the work in the open repositories of The Energy Mashup Lab. NIST has  
678 incorporated that code into their TE Market simulation model.

679 The initial draft of CTS 1.0 (this specification) was based on clarifications and simplifications  
680 discovered building the internal services and APIs of that project. The Lab has continued to  
681 refine that work through and with the NJIT Capstone Projects.

682 All work continues in the open GitHub repositories, and all code is licensed under an Apache 2.0  
683 license.

684 The following individuals have participated in the creation, refining, and implementation of this  
685 specification and are gratefully acknowledged:

- 686 • NIST, the National Institute of Standards and Technology, including
  - 687 ○ David Holmberg
  - 688 ○ Thomas Roth
- 689 • Members of the WS-Calendar, Energy Market Information Exchange, and Energy  
690 Interoperation TCs (see acknowledgement in the respective specifications)
- 691 • Members of the NIST Transactive Energy Challenge Common Transactive Services work  
692 group (see acknowledgement in the respective specification and paper)
- 693 • New Jersey Institute of Technology and the NJIT Capstone program where The Energy  
694 Mashup Lab worked with faculty, staff, and teams of Seniors and Masters students,  
695 specifically
  - 696 ○ Professor Osama Eljabiri
  - 697 ○ Capstone Executive Team members for each term listed below
  - 698 ○ Team Members Fall 2020: Omair Abdul, Omar Janouk, Matthew Molinari
  - 699 ○ Team members Summer 2020: Indira A. Akkiraju, Josiah Nieves, Alex Shepherd
  - 700 ○ Team members Spring 2020: Matt Amato, Dhruvinkumar Desai, Anupam Saini,  
701 Justin Schuster
  - 702 ○ Team members Fall 2019: Rajeev Chanchlan, Jasper Sam David, Mounica Gona,  
703 Dhrumil Shah, Karan Shah
- 704 • The Energy Mashup Lab, its officers and associates

## 708 **Appendix B. Background and Development history**

709 The Common Transactive Services (CTS) are a lightweight profile of the OASIS Energy  
710 Interoperation Standard [EnergyInterop].

711 The Energy Interoperation Technical Committee was formed to define the necessary interactions  
712 between Smart Grids and their end nodes, including Smart Buildings, Enterprises, Industry,  
713 Homes, and Vehicles. The specification defines data and communication models that enable  
714 standard exchange of signals for dynamic pricing, reliability, and emergencies. Energy  
715 Interoperation supports market-based balancing of energy supply and demand while increasing  
716 fluidity of contracts.

717 In 2015, the US National Institute for Standards and Technology (NIST) began the Transactive  
718 Energy Modeling and Simulation Challenge (TE Challenge). A report delivered to the TE  
719 Challenge and a paper delivered to the Transactive Energy Systems Conference [**TESC2016**]  
720 defined a minimal subset of Energy Interoperation, which became known as the common  
721 transactive services. The report further showed commonality between the messages of existing  
722 TE systems, including several not based on Energy Interoperation.

723 The Energy Mashup Lab has created an open source implementation using the Common  
724 Transactive Services called EML-CTS<sup>15</sup>, which has in turn helped us to further simplify the  
725 original description of CTS and led to this evolved specification.

726 The EML-CTS v1.0 system uses CTS message payloads expressed in JSON for all market  
727 communications. The Lab plans to contribute this specification to the OASIS Energy  
728 Interoperation Technical Committee as the basis for work on a standard lightweight specification  
729 for The Common Transactive Services.

## 730 Appendix C. Glossary

- 731 No definition in this glossary supplants normative definitions in this or referenced specifications.  
732 They are here merely to provide a guidepost for readers at to terms and their special uses.  
733 Implementers will want to be familiar with all referenced standards.
- 734 Actor is an architectural component that interacts with other actors. Actors may take on roles,  
735 e.g. as a Party in a transaction.
- 736 Agreement is broad context that incorporates market context. Agreement definitions are out of  
737 scope in the Common Transactive Services.
- 738 EMIX: As used in this document, EMIX objects are descriptions applied to a WS-Calendar  
739 Sequence. EMIX defines Resource capabilities, used in tenders to match capabilities to  
740 need, and in Products, used in tenders and in specific performance and execution calls.  
741 Please note that CTS uses more recent WS-Calendar specifications than that used in  
742 EMIX, and that the product definition in CTS 1.0 is implicit.
- 743 Party or Transactive Party is a role that an actor may take. In the EML-CTS implementation, the  
744 Local Market Agent (LMA) is not a party, but the Transactive Energy User Agent  
745 (TEUA) is a party and represents its Energy Manager.
- 746 Resource (as defined in EMIX<sup>16</sup>): A Resource is something that can describe its capabilities in a  
747 Tender into a market. How those Capabilities vary over time is defined by application of  
748 the Capability Description to a WS-Calendar Sequence. See [EMIX].
- 749 Stream: A set of contiguous intervals of the same size. See [Streams]
- 750 Tender: A tender is an offering for a Transaction. See Transaction.
- 751 Transaction: A binding commitment between parties entered into under an agreement.
